Thomas Jefferson national accelerator facility

Jefferson lab

Located in Newport News, Virginia, Jefferson Lab is home to an electron accelerator that support four experimental halls [1].

The continuous electron beam accelerator facility

Continuous electron beam accelerator facility (CEBAF)

CEBAF consists of two linacs making an ~ 1.4 km racetrack shaped, electron accelerator capable of producing an ~ 12 GeV electron beam.

The GlueX Bremsstrahlung photon beamline

Beamline overview

The GlueX beamline consists of a thin diamond radiator held by a goniometer from which a polarized photon beam is created through the bremsstrahlung process. Scintillating detectors are used to reconstruct the photon beam energies and a silicon strip detector is used to determine photon beam polarization [2].

The GlueX spectrometer

GlueX spectrometer overview

The GlueX spectrometer consists of six sub-detectors. A cryogenic hydrogen target is inserted into a tracking volume such that it is surrounded by the central drift chamber, the barrel calorimeter, and a superconducting solenoid. The forward drift chamber caps the downstream end of the tracking volume. The forward calorimeter and time of flight planar detectors cover the downstream end of the hall [3].

Goals of the GlueX experiment

Goals

- 1 Map the light meson spectrum.
- 2 Find hybrid mesons with exotic quantum numbers [4].

The Standard Model^[5]

Standard Model of Elementary Particles

Baryon

Meson

Glueball

Hybrid

Tetraquark

Hadronic Molecule

Meson nonets

Murray Gell-Mann, Yuval Ne'eman, George Zweig, and Kazuhiko Nishijima

- Gell-Mann and Nishijima - *strangeness* to describe long lived particles.
- Gell-Mann and Ne'eman - *the eightfold way* in 1961.
- Gell-Mann and Zweig - *multiplets* using electrical charge and strangeness [7] [8].

Constituent quark model

Murray Gell-Mann and George Zweig

- A result of explaining ϕ meson preferential decay to two kaons.
- Gell-Mann and Zweig - *quarks* are the building blocks of hadrons^a.
- Quarks - spin- $\frac{1}{2}$ particles consisting of *up*, *down*, and *strange*.
- No free quarks, *confined* to hadrons.
- Restricts possible J^{PC} quantum numbers [9].

^aZweig called them *aces*.

Mesons in constituent quark model

J^{PC} quantum numbers

S - Intrinsic spin

L - Orbital angular momentum

J - Total angular momentum

$$J = L \oplus S$$

P - Parity $P = (-1)^{L+1}$

C - Charge conjugation

$$C = (-1)^{L+S}$$

Possible J^{PC}

According to the rules of the constituent quark model, can only have radial and orbital excitations. For meson states, this means only:

$$0^{-+}, 0^{++}, 1^{--}, 1^{+-}, 2^{--}, 2^{-+}, 2^{++}, 3^{--}, \dots$$

J^{PC} quantum numbers are allowed, leaving:

$$0^{--}, 0^{+-}, 1^{-+}, 2^{+-}, 3^{-+}, \dots$$

as forbidden by the constituent quark model.

S	L	J	P	C	J^{PC}	Meson type
0	0	0	-	+	0^{-+}	pseudoscalar
1	0	0	-	-	1^{--}	vector
0	1	1	+	-	1^{+-}	pseudo-vector
1	1	0	+	+	0^{++}	scalar
1	1	1	+	+	1^{++}	axial vector
1	1	2	+	+	2^{++}	tensor

Baryon

Meson

Glueball

Hybrid

Tetraquark

Hadronic Molecule

HadSpec predictions

Interpretation

J^- on left, J^+ middle, and exotic quantum numbers right. Hybrid mesons are marked in orange and possible strange quark contributions are marked in green [10].

Light meson spectrum

Orbital and radial excitations

Orbital excitations are displayed by the y-axis and radial excitations are shown on the x-axis. The figure displays spectroscopic notation ${}^{2S+1}L_J$, J^{PC} of the nonet, and the name of the states. If shown in black, the state is well established. If you include exotic quantum numbers, this adds many more mesons are added [TDR].

The E/ι puzzle

Pseudoscalar in $\bar{p}p$ annihilation at rest

In 1963, peak at 1425 MeV seen in $K\bar{K}\pi$ mass spectrum with $J^{PC} = 0^{-+}$ dubbed E meson [11].

E and ι separate particles

Different quantum numbers for different production mechanisms from spin-parity analysis, specifically the E meson 0^{-+} and the ι meson 1^{++} [11].

The 1998 PDG

The 1998 PDG reports an axial vector $f_1(1420)$ and pseudoscalar $\eta(1440)$ as the ι and E , respectively [12].

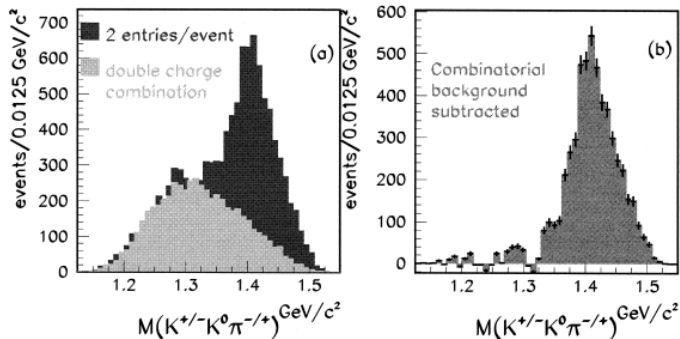

J/ψ decays at MARKIII

Two pseudoscalars in $K\bar{K}\pi$

Reported pseudoscalars at 1416 MeV and 1490 MeV decaying $a_0(980)\pi$ and $K^*(892)\bar{K}$ in J/ψ decays [13]. Confirmed by DM2 experiment [14].

$\bar{p}p$ collisions in Obelix

OBELIX evidence of two pseudoscalar states in 1.4 – 1.5 GeV region

In $\bar{p}p$ annihilation at rest, OBELIX shows evidence of two pseudoscalar mesons decaying $K\bar{K}\pi$ in the mass region of interest [11].

$\gamma\gamma$ collisions in L3

Evidence of $\eta(1475)$ in $\gamma\gamma$ collisions

The L3 collaboration shows evidence of $\eta(1475)$ in $\gamma\gamma$ collisions, but not the $\eta(1405)$. This supports the argument that $\eta(1405)$ consists only of gluonic content [15].

E852 at Brookhaven PWA results

PWA of $K^+K^-\pi^0$

Evidence of $\eta(1295)$ and $f_1(1285)$ decay $a_0(980)\pi^0$ left. Evidence of $\eta(1416)$ decay $a_0(980)\pi^0$ and $K^*\bar{K}$, and $\eta(1485)$ and $f_1(1420)$ decay $K^*\bar{K}$ right [16].

Interpretation of previous results

The $\eta(1295)$ and $\eta(1475)$ pseudoscalars

The existence of the $\eta(1295)$ seen in $\pi^- p$, J/ψ decays, and B meson decays is debated. Assuming the $\eta(1295)$ exists, then it may be the first radial excitation of η and the $\eta(1475)$ is the first radial excitation of η' . The $\eta(1475)$ isoscalar would be the $s\bar{s}$ contribution to the 0^{-+} nonet.

The $\eta(1405)$ pseudoscalar

If two pseudoscalar mesons exist in the 1400 MeV region, the $\eta(1405)$ might be something other than a meson, specifically 0^{-+} glueball. This is supported by the fact that it is not seen in $\gamma\gamma$ collisions in L3. This is not supported by lattice gauge theory, but is by the flux tube model [17].

Motivation for the analysis of $\gamma p \rightarrow pK^+K^-\gamma\gamma$ events

Analysis of $X \rightarrow K^*\bar{K}$

- 1 Do two pseudoscalar mesons exist in the 1400 MeV region seen in production mechanisms: π^-p , radiative $J/\psi(1S)$ decay, and $\bar{p}p$ annihilation at rest?
- 2 What additional states can be found in the mass range used in this analysis?

We perform a partial wave analysis in search of mesons decaying $K^*\bar{K}$ to answer these questions [TDR].

Reconstruction

Charged particles

Charged particles are reconstructed using a helical fit of their points of detection in the CDC and other detectors. This fit is dependent on the assumed identification of a particle. If the fit converges, the identification hypothesis and its respective kinematic information is kept.

Neutral particles

Neutral particles are reconstructed using their electromagnetic showers in BCAL and FCAL.

Events

Events are produced based on combinations of the charged tracks and neutrals, coupled with the beam photons in time with the event. This is a combinatorial problem since the selection of charged and neutral particles comes from a set larger than what is required for a reaction.

Beam photons

Beam photon selection

Beam photons in time with detected events fall between -2.004 and 2.004 ns, surrounded by side-band peaks from out of time beam photons. One photon is selected per event with signal photons receiving a weight of 1 and side-band photons are given a weight of $-f/N_a$, where N_a is the number of accidental side-bands used and f is a correction factor. For PWA, photons with energies from $8.2 - 8.8$ GeV are selected.

Selection of tracks in time with beam photons

Δt for a charged tracks or neutrals

The time for an event at the vertex is determined by propagating back to the vertex within the target volume. From the tracking reconstruction, it is possible to determine the time an event occurs for each particle hypothesis. The distribution is centered over zero for the correct particle identification.

Detector	Δt_p (ns)	Δt_{K^\pm} (ns)	Δt_γ (ns)
BCAL	± 0.5	± 0.2	± 2.0
FCAL	± 1.0	± 0.5	± 2.0
TOF	± 0.3	± 0.15	NA
ST	None	None	NA
NULL	None	None	NA

Event selection

Removal conditions

$$\chi^2/n.d.f. > 5$$

$$\theta_\gamma < 1.5^\circ$$

$$10.3^\circ < \theta_\gamma < 11.5^\circ$$

$$E_{BCAL}^{min} < 0.05 \text{ GeV}$$

$$\text{Shower quality FCAL} < 0.5$$

$$d_{\gamma_1, \gamma_2} < 12.5 \text{ cm}$$

$$MM^2 > 0.2 \text{ GeV}$$

$$p_p^{recoil} < 0.45 \text{ GeV}$$

$$52 \text{ cm} < z_{vertex} > 78 \text{ cm}$$

$$r_{vertex} > 1 \text{ cm}$$

Selection of combination

Combination with best $\chi^2/n.d.f.$ from kinematic fit is selected.

Kinematic fitting

Kinematic fitter

A four-momentum and vertex kinematic fit is performed through a χ^2 minimization, determined by

$$\chi^2 = (\eta_0 - \eta_f)^T \mathbf{G}_y (\eta_0 - \eta_f)$$

where η_0 is the vector of the quantity values before the fit, η_f is the vector of the quantity values after the fit, and G_y is the inverse of the covariance matrix for those quantities.

$$\pi^0 \rightarrow \gamma\gamma$$

π^0 selection

From Gaussian with third degree polynomial fit, π^0 mesons is selected using 2σ from center, 0.12 – 0.15 GeV as shown by dashed lines.

$$K^*(892) \rightarrow K\pi^0$$

$K^*(892)$ selection

From Gaussian with third degree polynomial fit, $K^*(892)$ mesons is selected using 2σ from center, 0.84 – 0.94 GeV as shown by dashed lines.

Excited K^*

A peak for excited K^* mesons near ~ 1.4 GeV is visible. This may include $K_1^*(1410)$, predicted to be an η_1' hybrid meson candidate decay product.

$$X \rightarrow K^{*\pm}(892)K^{\mp}$$

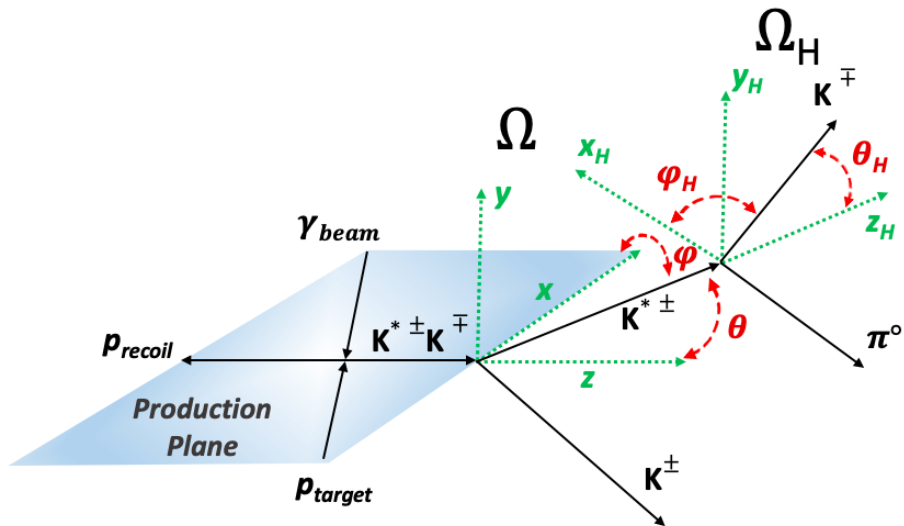

Possible meson states

Visible peak near ~ 1.4 GeV for both distributions. This is consistent with $\eta(1405)$, $f_1(1420)$, $\rho(1450)$, and $\eta(1475)$. Difficult to make any other conclusions for higher mass peaks without PWA.

Angular distributions

Angular distributions cont.

$K^* \bar{K}$ Monte Carlo

Generator and simulation

- Randomly generate samples of $K^* \bar{K}$ isotropically through phase space.
- Pass generated events through simulation of GlueX spectrometer.
- Flat incident photon beam energy from 8.2 – 8.6 GeV.
- The K^* mass distribution is given a Breit-Wigner shape.
- t -slope = $1.3/\text{GeV}^2$

$K^* \bar{K}$ Monte Carlo cont.

Intensity function in reflectivity basis requiring positive reflectivity

Obtain fit parameters $[J_i^P]_{m,k}^{(\epsilon)}$ for different wave contributions with fits to the angular distributions using the intensity function:

$$I(\Omega, \Omega_H, \Phi) = 2\kappa \sum_k [(1 - P_\gamma) [| \sum_{i_N, m} [J_i^N]_{m,k}^{(+)} \text{Im}(Z) |^2 + | \sum_{i_U, m} [J_i^U]_{m,k}^{(+)} \text{Re}(Z) |^2] + (1 + P_\gamma) [| \sum_{i_U, m} [J_i^U]_{m,k}^{(+)} \text{Im}(Z) |^2 + | \sum_{i_N, m} [J_i^N]_{m,k}^{(+)} \text{Re}(Z) |^2]],$$

where

$$Z = e^{-i\Phi} \sum_{m_2''} \sum_{m'} D_{mm'}^{J_i^*}(\Omega) \langle Jm' | j_1 m_1 j_2 m_2'' \rangle D_{m_2'', m_2}^{j_2^*}(\Omega_H) [18].$$

Partial wave analysis cont.

Quantum numbers

- J and M are the total angular momentum and spin projection of the meson resonance.
- L and m_L are the orbital angular momentum and spin projection of the meson resonance's decay, for which a P
- S and m_S are the spin and spin projection of the vector meson.

Wave conditions

- Require positive reflectivity.
- $J = 0, 1,$ and 2 for spin projections M from $-J$ to J are included for the four coherent sums.
- To reduce fit parameters, the orbital angular momentum of the decay L is restricted to $P, S,$ and D waves for each J , respectively.
- To conserve total angular momentum $M = m_L + m_S$.

J	M	L	m_L	S	m_S
0	0	1	-1	1	1
0	0	1	0	1	0
0	0	1	1	1	-1
1	-1	0	0	1	-1
1	0	0	0	1	0
1	1	0	0	1	1
2	-2	2	-2	1	0
2	-2	2	-1	1	-1
2	-1	2	-2	1	1
2	-1	2	-1	1	0
2	-1	2	0	1	-1
2	0	2	-1	1	1
2	0	2	0	1	0
2	0	2	1	1	-1
2	1	2	0	1	1
2	1	2	1	1	0
2	1	2	2	1	-1
2	2	2	1	1	1
2	2	2	2	1	0

Unbinned extended maximum likelihood fit

The likelihood is defined in terms of the intensity as

$$-2 \ln \mathcal{L} = 2\mu - 2 \sum_{i=1}^n \ln I(\Omega_i) + \text{constant}.$$

where 2μ is a normalization determined by Monte Carlo integration, the sum is produced from the data, and the constant is ignored since it has no effect on minimization. The expected number of events μ as a function of the angular distribution

$$\mu = \int d\Omega I(\Omega) \eta(\Omega),$$

where η efficiency correction term.

Fit constraints

Between coherent sums

- Four fit parameters, two $[J_i^N]^{(+)}$ and two $[J_i^U]^{(+)}$.
- Identical fit parameters constrained.

Simultaneous fit

- Data broken into eight subsets with meson resonance decays $K^{*+}K^-$ and $K^{*-}K^+$ for each polarization.
- Identical fit parameters between the eight subsets are constrained.
- $J = 0$ with P -wave forced to real.
- Number of fit parameters reduced from 192 to 10.
- Simultaneous fit between these subsets of the data reduces statistical uncertainty.

PWA fit results for

Uncertainty determination

Fit

Plot $\cos\theta$, $\cos\theta_H$, ϕ , and Φ of PWA fit results for all subsets. Fit histograms to the data. Extract fractional uncertainties of the coefficients.

$$h_{tot} = a_0 h_0 + a_1 h_1 + a_2 h_2 + C$$

$$\sigma_m = \frac{\sigma_{a_n}}{a_n} m$$

$K^* \bar{K}$ invariant mass for each total angular momentum

Results of PWA

- $J = 0$: Evidence of $\eta(1405)$ and $\eta(1475)$.
- $J = 1$: Evidence of $f_1(1420)$ and $f_1(1510)$.
- $J = 2$: Evidence of $f_2(1430)$ and $f_2(1530)$.

Invariant mass fit results

Results of PWA

Motivation revisited

Analysis of $X \rightarrow K^* \bar{K}$

- 1 Do two pseudoscalar mesons exist in the 1400 MeV region seen in production mechanisms: $\pi^- p$, radiative $J/\psi(1S)$ decay, and $\bar{p}p$ annihilation at rest?
- 2 What additional states can be found in the mass range used in this analysis [**TDR**]?

$J = 0$ states

$J=0$ results

- Two pseudoscalar mesons in 1400 MeV mass region.
- Is the $\eta(1405)$ or the $\eta(1475)$ the $s\bar{s}$ contribution to the first radially excited pseudoscalar nonet?
- What about the glueball state explanation since this is produced in photoproduction? Is this an example of Pomeron exchange [**TDR**]?

$J = 1$ states

$J=1$ results

- Two axial vector mesons in 1400 – 1500 MeV mass region.
- Is the $f_1(1420)$ or $f_1(1510)$ the $s\bar{s}$ contribution to the axial vector meson nonet?
- Can the $f_1(1510)$ be firmly established [TDR]?

$J = 2$ states

$J=2$ results

- Two tensor mesons in 1400 – 1500 MeV mass region.
- Can we establish $f_2(1430)$ in a new decay mode?
- If the $f_2(1430)$ exist, is it or the $f_2'(1525)$ the $s\bar{s}$ contribution to the tensor meson nonet [TDR]?

Resolving the nonets

How can this be resolved?

The K_L would help establish the $s\bar{s}$ meson contributions to the pseudoscalar, axial vector, and tensor meson nonets. The extraneous states would require glueball, hadronic molecule, or tetraquark explanations [TDR].

Completed

- Multiple states identified in the 1400 – 1500 MeV mass region.
- These states are consistent with past results.
- Consistent pattern between the three nonets.

Future

- Future work will move up the $K^*\bar{K}$ mass spectrum.
- Look at the other meson resonance decays, $a_0\pi^0$ and $K^+K^-\pi^0$.
- Can the group provide evidence of the η'_1 hybrid meson candidate?

LQCD hybrid predictions

Masses

$$0^{+-} \sim 2.3 - 2.5 \text{ GeV}$$

[1] C. Meyer *et al.*, [arXiv:1004.551].

Partial wave analysis

The intensity of a meson states production is defined in terms of the differential cross section:

$$I(\Omega, \Omega_H, \Phi) \equiv \frac{d\sigma}{dt dm_{K^* \bar{K}} d\Omega d\Omega_H d\Phi}.$$

In terms of phase rotated decay amplitudes

$\tilde{A}_{\pm}(\Omega, \Omega_H, \Phi) = e^{\mp i\Phi} A_{\pm}(\Omega, \Omega_H, \Phi)$ in a reflectivity basis

$$\begin{aligned} I(\Omega, \Omega_H, \Phi) = & 2\kappa \sum_k [(1-P_\gamma) | \sum_{i_N, m} [J_i^N]_{m, k}^{(+)} \text{Im}(Z) + \sum_{i_U, m} [J_i^U]_{m, k}^{(-)} \text{Im}(Z) |^2 \\ & + | \sum_{i_N, m} [J_i^N]_{m, k}^{(-)} \text{Re}(Z) + \sum_{i_U, m} [J_i^U]_{m, k}^{(+)} \text{Re}(Z) |^2] + (1+P_\gamma) [| \sum_{i_N, m} [J_i^N]_{m, k}^{(-)} \text{Im}(Z) \\ & + \sum_{i_U, m} [J_i^U]_{m, k}^{(+)} \text{Im}(Z) |^2 + | \sum_{i_N, m} [J_i^N]_{m, k}^{(+)} \text{Re}(Z) + \sum_{i_U, m} [J_i^U]_{m, k}^{(-)} \text{Re}(Z) |^2]. \end{aligned}$$

$$A_\lambda = \sum_i \sum_m T_{\lambda, m}^i \sum_\lambda D_{m, \lambda}^{J_i^*}(\Omega) F_\lambda^i D_{m, \lambda}^{1*}(\Omega_H), \quad (1)$$

Unbinned fitting

Unbinned extended maximum likelihood fit

The expected number of events μ as a function of the angular distribution

$$\mu = \int d\Omega I(\Omega)\eta(\Omega),$$

where η efficiency correction term.

Likelihood

The likelihood is defined in terms of the intensity as

$$\mathcal{L} = \frac{e^{-\mu}}{n!} \prod_{i=1}^n I(\Omega_i),$$

which by Sterling is

$$-2 \ln \mathcal{L} = 2\mu - 2 \sum_{i=1}^n \ln I(\Omega_i) + \text{constant}$$

where 2μ is a normalization determined by Monte Carlo integration, the sum is produced from the data, and the constant is ignored since it has no effect on minimization.

Why a polarized photon beam?

Photon beam

Pion beam has anti-aligned spins ($S = 0$), while photon beam is a virtual meson with aligned spins ($S = 1$). Starting with $J^{PC} = 1^{--}$ allows for mesons with exotic quantum numbers that are suppressed by a pion beam.

Linear polarization

Linearly polarized states are eigenstates of parity. Orientation of linear-polarization maps onto the naturality of the exchange particle (Natural: $J^P = 0^+, 1^-, 2^+, \dots$ and Unnatural: $J^P = 0^-, 1^+, 2^-, \dots$) [GlueX TDR].

$\phi\pi^0$ decay in Serpukhov data

Serpukhov analysis

The Serpukhov figure shows the (a) $C(1480)$ invariant mass distribution from fits the ϕ distribution to remove background. The (b) acceptance for $\phi\pi^0$ and a (c) false " ϕ " π^0 from mis-identification of kaons are also shown. The $C(1480)$ is not seen in $\bar{p}p$ experiment and not seen by E852 [Serpukhov]. The PDG reports the $C(1480)$ as the $\rho(1570)$ seen in $\eta\rho \rightarrow \eta\pi\pi$.

[1] S. Bitjukov *et al.* (SERPUKHOV), Phys. Lett. **B188**, 383 (1987).

$\phi\pi^0$ decay in E852 data

E852 analysis

The left figure shows the side-band study divided $K\bar{K}$ mass spectrum divided into three 10 MeV bins from (a) 1.0 – 1.01 GeV, (b) 1.015 – 1.025 GeV, and (c) 1.03 – 1.04 GeV. The background subtraction is shown in (d). The right figure shows the PWA study using $\phi\pi^0$ S and P waves [E852].
