

Today: X-rays

# Contrast media

Contrast between different kinds of soft tissue is poor. In order to see structure of soft tissue when using X-rays a contrast medium can be used.

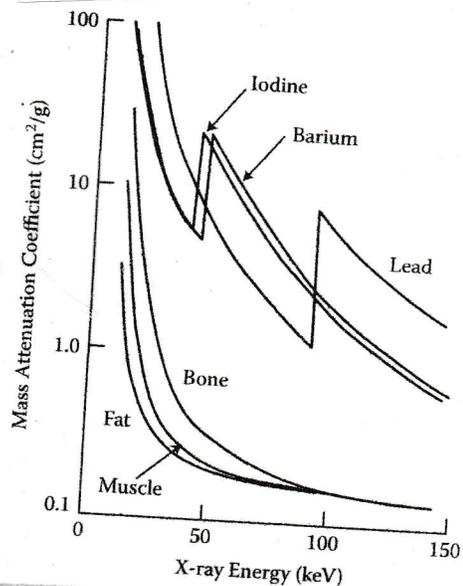

Contrast media are designed to be nontoxic compounds in liquid form that stay in body long enough for image formation, then excreted naturally.

Most common elements used

\* Barium ( $Z=56$ )

\* Iodine ( $Z=53$ )

The absorption edges are in the range of a typical diagnostic X-ray source  $\Rightarrow$  Enhances interaction even more 😊

For gastrointestinal tract, a drink or enema can be used as a delivery system

For urinary tract, iodine is commonly used & administered by injection. There are two types

- \* Ionic  $\rightarrow$  Can be dangerous (1 in 40,000 chance of death)
- \* Nonionic  $\rightarrow$  Safer but more expensive

# Generation of x-rays

103

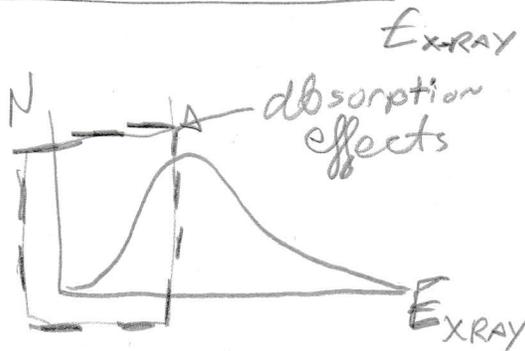

1<sup>st</sup> produce free electrons by "boiling" them off of a fine filament of tungsten by passing electric current through filament. ← cathode

An electric potential [voltage] applied to the liberated electrons & accelerates them between cathode & anode

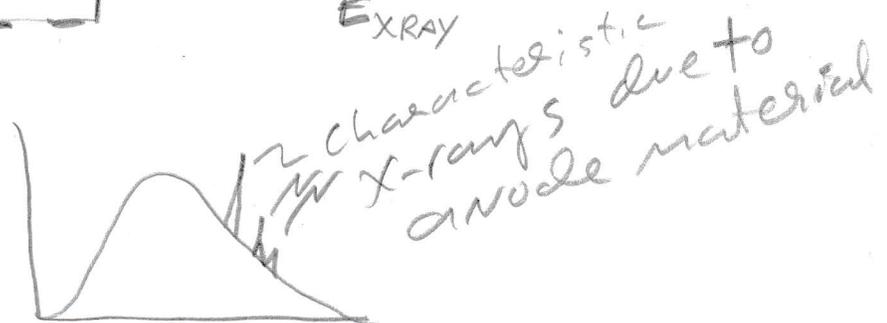

The electrons are slammed into anode & release energy through bremsstrahlung (braking radiation)

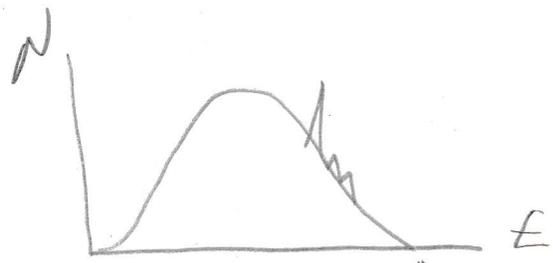

For lowest energies, photons are absorbed so

But Also characteristic x-rays

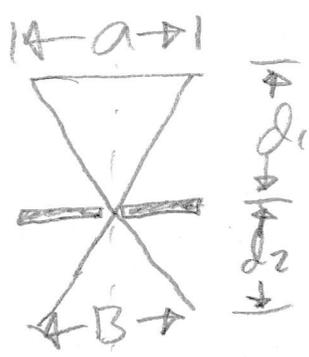

highest energy is determined by the accelerating potential

Characteristic X-rays:

- \* Free electron collides with inner atomic electron & ejects that electron
- \* Atomic electron from another orbital "jumps down" to fill hole left by ejected electron.

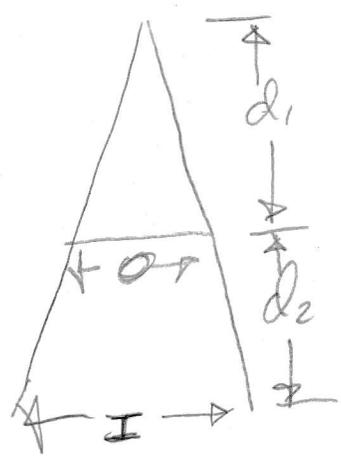

Blur

Focal spot a results in blurring of point-like features.

$$\frac{a}{d_1} = \frac{B}{d_2} \Rightarrow B = a \frac{d_2}{d_1}$$

# Magnification

$$\frac{I}{d_1+d_2} = \frac{O}{d_1}$$

⊄ M ≡ magnification

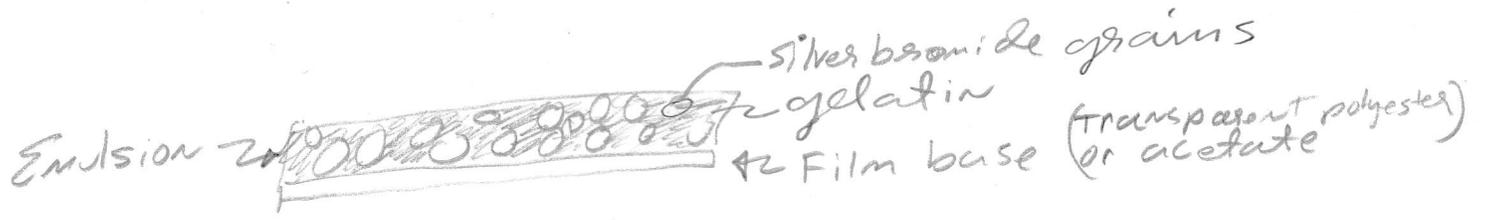

$$\& M \equiv \frac{I}{O}$$

$$\Rightarrow M = \frac{d_1+d_2}{d_1}$$

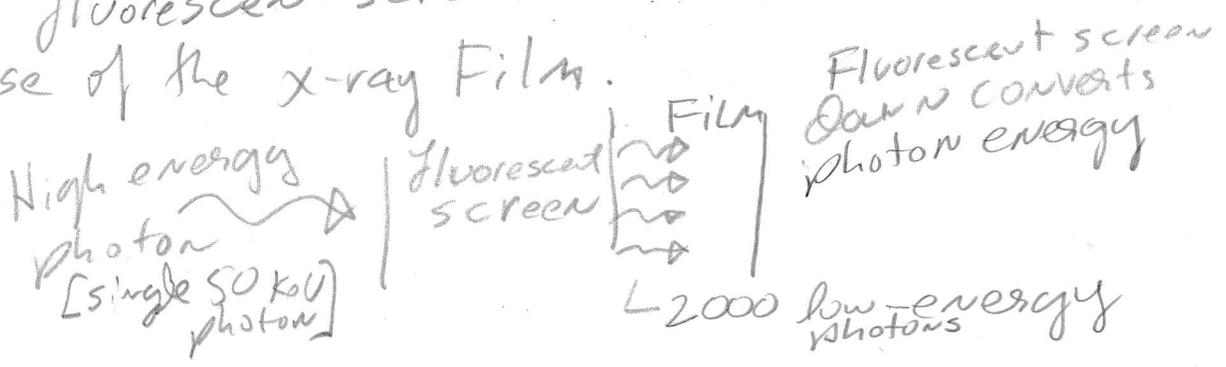

# X-ray Detectors

**Film:** Imaging Chest & lungs, skeleton, gastrointestinal tract, & in dentistry

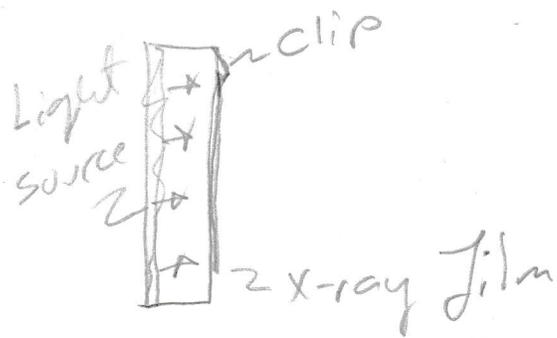

Good spatial resolution & sensitivity  
 & low price & wide availability & permanency for record keeping

A fluorescent screen can enhance the response of the x-ray film.

x-ray film are typically viewed through a light box

Perceived transparency & opaqueness made quantitative using

Optical Density  $\equiv$  OD

$$OD = \log \frac{I_0}{I} \quad \text{where}$$

$I_0 \equiv$  intensity before film

$I \equiv$  intensity after film

### Digital Radiography

Radiography that uses electronic detectors instead of film  $\rightarrow$  Becoming more & more common

Computed Radiography  $\equiv$  CR require further processing & often use "storage phosphors" that can replace screen-film cassettes in existing x-ray systems

Electronic point detectors only measure x-ray transmission through a line. For image formation it is required that an array and/or scan be created

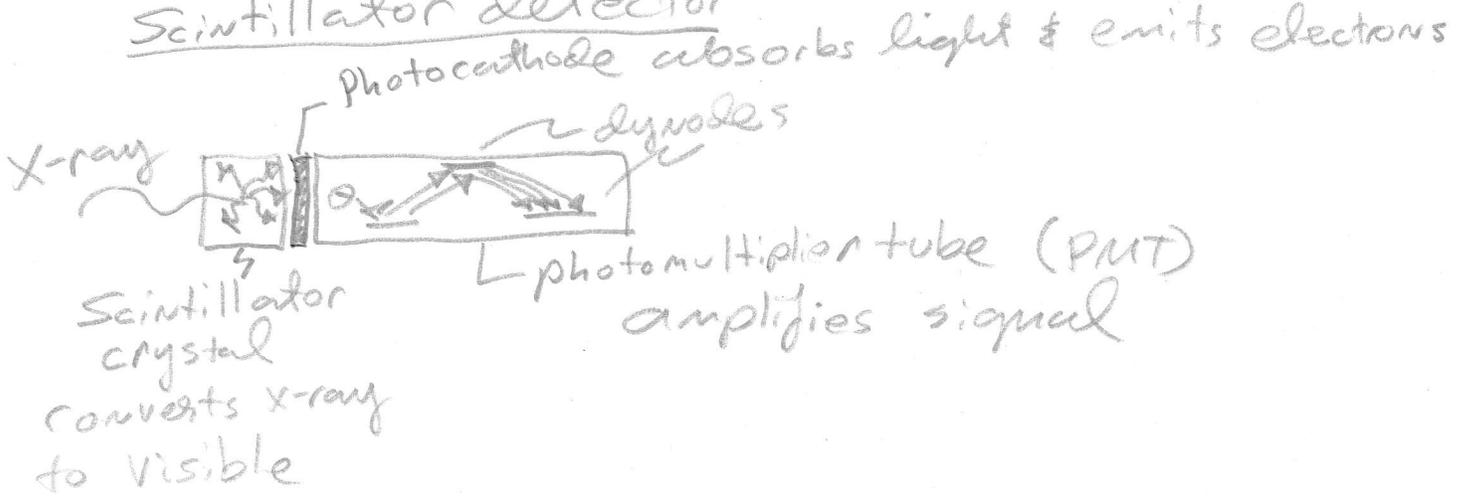

# Electronic point detectors

Two popular choices:

- \* Scintillators
  - \* Gas ionization detectors
- } Electronic signal is proportional to x-ray intensity.

More complex than film BUT are better at distinguishing between low contrasting media

## Scintillator detector

## Gas ionization detector
